Response to reviewers

*We are **grateful and thank** Reviewer #2 and Associate Editor for thorough assessment of our manuscript and for providing us constructive comments and suggestions.*

*In the revised version, **all the comments and suggestions have been taken into account** and changes have been made to improve the presentation.*

We now add point-by-point reply (in italics, in red color fonts) to the comments and suggestions of the reviewer #2 and Associate Editor and make clear where and what changes have been made in the revised version of the manuscript.

Reviewer #2

Major suggestion

Comment 1: The authors have adequately addressed all but one of my comments. In response to my comment on Figure 2, the authors state:

"The revised Figure 2d shows the portion of the gully system that was selected for measurement."

But the revised Figure 2d is nearly identical to the original Figure 2d, and this doesn't address the issue I raised in the original review: the fans shown here clearly interfinger and there appears to be a lot of evidence of crosscutting.

Perhaps you could annotate the figure with an outline of the gully system(s) you investigated? This would help to illustrate what you mean with the text on lines 152-154.

Response 1: *Done. As suggested, we have annotated the gully systems that were investigated in this study. Please see the revised figure 2. Also, in the caption of Figure 2, we have added the following:*

'The dashed lines show the gully systems that were investigated in this study.'

Please see line no. 126-127.

Minor suggestions

Comment 1: Responding to the author's responses on comments 9 and 12: The lighting and shadows make it impossible to tell from Fig 4 whether these gullies are V or U shaped, so the reader has to take

your word for it. For example, if it weren't for the label I might have assumed that the gullies in Figure 4d were an example of a U-shape. A topographic cross-section would be helpful for illustrating the differences.

Response 1: *Done. As suggested, we have added a 'topographic profile' to illustrate the V-shaped incision. We have added the following in the caption of Figure 4 (line no. 218-219):*

Note the topographic profile (A-A`) in Figure 4e that illustrates V-shaped incision of the gully channel.

Comment 2: Line 285: "deposits are having an elongated" -> "deposits have an elongated".

Response 2: *Done. Changed 'are having' to 'have'. Please see line no. 336.*

Comment 3: Line 366: I suggest changing "It is likely that the present-day sublimation of CO2 ice on Mars provided" to "Present-day sublimation of CO2 ice on Mars may have provided" (also in the abstract)

Response 3: *Done. Changed 'It is likely that the present-day sublimation of CO2 ice on Mars provided' to 'Present-day sublimation of CO2 ice on Mars may have provided' at both the places. Please see line nos. 418-419 and 25.*

Comment 4: Line 379: should "multiple formative mechanisms" be "multiple formative environments"? In the next paragraph you suggest that all of the gully systems were formed by debris flows (i.e., the same formative mechanism). I think that you are proposing that the difference is the geologic setting/environment, not the erosive process.

Response 4: *Agree. As suggested, we have changed 'multiple formative mechanisms' to 'multiple formative environments'. Please see line no. 432.*

Comment 5: Figures The figures (particularly the plots) are low resolution and appear somewhat pixelated. This may just be an issue in the PDF I am reviewing, but you may want to check prior to publication.

Response 5: *Sure. We have rechecked the resolution of the plots. They do not get pixelated at zoom level up to 150%.*

Comment 6: Figure 6: I still don't think this figure adds much. The interesting parts are already presented in Figure 5 (and the figure isn't really used other than lines 238-243). If you do keep the figure, I suggest the following: (1) add labels "Bedrock" and "LDM" to the Figure to make it more obvious without needing to read the caption. (2) Also move (a) and (b) to the upper left of each frame for consistency with other figures. (3) rotate the labels along the diagonal by ~30° to make it more obvious that they are referring to the columns.'

Response 6: *Done. As suggested, we have (a) added labels 'Bedrock' and 'LDM/glacial deposits' to figures 'a' and 'b', respectively, (b) moved 'a' and 'b' to the upper left of each frame, and (3) rotated the labels diagonally by 30° to illustrate that the labels correspond to the columns. Please see the revised Figure 6.*

Associate Editor

Line comments:

Comment 1: L14: either 'consisting of ice' or 'comprising ice'

Response 1: *Done. Changed 'consisting of ice'. Please see line no. 14.*

Comment 2: L17: alcove and fan > the alcoves and fans

Response 2: *Done. Changed 'alcove and fan' to 'the gully alcoves and fans'. Please see line no. 17.*

Comment 3: L20: that mean gradient > that the mean gradient

Response 3: *Done. Added 'the'. Please see line no. 20.*

Comment 4: L33: incised into the > incised into:

Response 4: *Done. Deleted 'the'. Please see line no. 33.*

Comment 5: L34-35: The citations currently used are for one specific type of glacial deposit (GLFs), which don't seem to be the focus of this manuscript. More appropriate would be references to LDAs. But more specifically papers which show the glacier-gully interactions. For example Conway et al. 2018, de Haas et al. 2017 etc.

Response 5: *Done. Changed 'Hubbard et al., 2011; Souness et al., 2012; Souness and Hubbard, 2012' to 'Conway et al., 2018' and 'de Haas et al., 2019a'. Please see line no. 34-35.*

Comment 6: L47: (VFF) > (VFFs)

Response 6: *Done. Changed 'VFF' to 'VFFs'. Please see line no. 46.*

Comment 7: L48: extent of latitudes > latitude ranges (It would be good to state the latitude range here.)

Response 7: *Done. Added 'between 30°-60°'. Please see line no. 47.*

Comment 8: L49: This is the first in-text use of lobate debris apron, so define LDA acronym here.

Response 8: *Done. Defined 'LDA as lobate debris aprons' at 48.*

Comment 9: L49: fill > fills

Response 9: *Done. Changed 'fill to 'fills'. Please see line no. 49.*

Comment 10: L51: Conway et al. 2018 citation is not a suitable reference for this statement. You could refer to SHARAD papers, which infer high purity ice and thin debris cover. E.g.:

Holt et al. 2008 https://doi.org/10.1126/science.1164246; Plaut et al 2009

https://doi.org/10.1029/2008GL036379; Petersen et al. 2018 https://doi.org/10.1029/2018GL079759

Response 10: *Done. Replaced 'Conway et al., 2018' with 'Plaut et al., 2009'. Please see line no. 50.*

The suggested reference has been added in the list of references.

Comment 11: L70 & 81: morphology and morphometry > morphologies and morphometries

Response 11: *Done. Changed 'morphology and morphometry' to 'morphologies and morphometries'. Please see line no. 69 and 80.*

Comment 12: L75: Gullies by studying long profiles of gullies > gullies by studying their long profiles

Response 12: *Done. Changed 'gullies by studying long profiles of gullies' to 'gullies by studying their long profiles'. Please see line no. 74.*

Comment 13: L81: southern hemisphere > southern hemisphere of Mars

Response 13: *Done. Added 'of Mars' after 'southern hemisphere'. Please see line no. 80.*

Comment 14: L83: digital terrain model (DTM) > digital terrain models (DTMs)

Response 14: *Done. Changed 'digital terrain model (DTM)' to 'digital terrain models (DTMs)'. Please see line no. 82.*

Comment 15: L88: DTMs are produced > we produced DTMs with

Response 15: *Done. Changed 'DTMs are produced' to 'we produced DTMs'. Please see line no. 87.*

Comment 16: Table 1, row 'Artik': See L49 comment about defining LDA earlier, and remove LDA definition from here.

Response 16: *Done. Removed 'LDA' definition from Table 1.*

Comment 17: L107-114: There are currently no in-text references to Fig 2b-d, please add

Response 17: *Done. Added in-text references for Fig. 2b, 2c and 2d. Please see line no. 106, 113, and 116.*

Comment 18: L107: 'alcoves on the walls': would it be better to say 'topographic depressions'? Alcoves is confusing if you don't necessarily mean gully alcoves.

Response 18: *Done. Changed 'alcoves' to 'gully alcoves'. Please see line no. 106. Also, checked the entire manuscript for consistency. 'Alcoves' have been changed to 'Gully alcoves'.*

Comment 19: L109-111: see above comments - you could just change alcoves to 'topographic depressions' to avoid this confusion?

Response 18: *We have changed 'alcoves' to 'gully alcoves' in the entire manuscript.*

Comment 19: L114: Could do with an extra phrase here - that they are also inferred to incise LDM? Your explanation in the response to reviewers was helpful in this regard, and this explanation would benefit from that addition in the manuscript itself.

Response 19: *Done. As suggested, we have added 'and are also inferred to incise LDM deposits'. Please see line no. 113-114.*

Comment 20: L115: Add reference to Fig 2d

Response 20: *Done. Added in-text reference to Fig. 2d. Please see line no. 116.*

Comment 21: L115: listed in LDM/glacial deposits > listed in criterion 1 (LDM/glacial deposits)

Response 21: *Done. Added 'criterion 1' before LDM/glacial deposits. Please see line no. 115.*

Comment 22: L122: delete the in 'the Terra Sirenum'

Response 22: *Done. Deleted 'in the Terra Sirenum'. Please see line no. 122.*

Comment 23: L122: delete 'evidence of'. The polygons are visible and are themselves evidence of LDM.

Response 23: *Done. Deleted 'Evidence of'. Please see line no. 122.*

Comment 24: L133: 'dimensionless variables' – give a couple of examples here?

Response 24: *Done. Added form factor, elongation ratio, and circularity ratio as examples of dimensionless variables. Please see line no. 134.*

Comment 25: Table 2 (and Figs 5, 6 & Table 3): Perimeter > Alcove Perimeter

Response 25: *Done. Changed 'Perimeter' to 'Alcove Perimeter' in Figs 5 and 6, and in Table 2 and 3.*

Comment 26: L155: HiRISE DTM that was used > HiRISE DTMs used for

Response 26: *Done. Changed 'HiRISE DTM that was used' to 'HiRISE DTMs used for'. Please see line no. 155-156.*

Comment 27: L157&158: source area is > source areas are

Response 27: *Done. Changed 'source area is' to 'source areas are' at both the places. Please see line no. 158 and 159.*

Comment 28: L167: Conway et al. 2015 isn't a seminal reference for CDA – provide one for CDA and/or make clear that this citation refers specifically to gullies.

Response 28: *Done. We have moved Conway et al., 2015 as the reference for line no. 171. Further, McLachlan, 2004 has been added as a reference for CDA. Please see line no. 168.*

McLachlan, G. J.: Discriminant analysis and statistical pattern recognition, John Wiley & Sons, 2005.

Comment 29: L174:

(a) LDM and VFFs > LDM and/or VFFs (you go on to say some aren't affected by both)

(b) Consider whether 'glacial deposits' would be better than VFFs. Are there locations where there are arcuate ridges and no accompanying VFFs? If so, 'glacial deposits' would be more appropriate as it covers both arcuate ridges and VFFs.

Response 29: *(a) Done. Added 'and' after LDM. Please see line no. 175.*

(b) VFFs were observed in nearly all the studied craters. So, we keep both arcuate ridges and VFFs.

Comment 30: L177: 4 craters out of 24 craters > 4 craters out of 24 craters influenced by LDM and/or VFFs (see also comment 174b above)

Response 30: *We cannot use and/or here because for these craters VFFs were not observed. These craters have gullies only influenced by LDM. Hence, we have not changed anything here in the manuscript.*

Comment 31: L233-234: Please fully describe the boxplot elements. e.g. Box shows interquartile range, central horizontal bar shows median, and whiskers show range.

Response 31: *Done. A suggested, we have rephrased the Figure caption as:*

The boxplot presented here shows interquartile range, central horizontal bar shows median, and whiskers show range of values of alcove/fan geometry, relief, gradient, and dimensionless variables of gullies incised into LDM/glacial deposits (pink) and bedrock (green).

Please see line no. 261-263.

Comment 32: L242: Define threshold for 'very strong positive correlation'

Response 32: *Done. Added '(>0.9)'as threshold for very strong positive correlation. Please see line no. 271.*

Comment 33: L245: What correlation coefficient is this? Pearsons?

Response 33: *Yes, Pearson correlation. We have added 'Pearson' in caption of Fig. 6 and in the text. Please see line no. 295.*

Comment 34: L246: Values approaching -1 are also strong, so reword this. e.g. 'Values approaching either 1 or -1 have stronger correlations. Zero indicates no correlation.'

Response 34: *Done. As suggested, we have added 'Values approaching either 1 or -1 have stronger correlations. Zero indicates no correlation' in the caption of Fig. 6. Please see line no. 296.*

Comment 35: L255: Is this an explanation of the 'weight'? If so, explain this after the first mention of weights (i.e. line 253). e.g. on line 253, you could say weight values indicate the discriminator power in separating between....' Then here, '...relief ratio (fan) have nearly 1/5 or greater (but less than 1/3) of the weight of alcove perimeter...'

Response 35: *Done. As suggested, we have added the following: ' Here, the weight values indicate the discriminator power in separating between the gullies formed in LDM/glacial deposits and bedrock'. Please see line no. 303-304.*

In the next line, rephrased the sentence as follows: 'The remaining variables such as fan relief, fan length, relief ratio (alcove), alcove width, and relief ratio (fan) have nearly 1/5 or greater (but less than 1/3) of the weight of alcove perimeter discriminatory power in separating between the gullies formed in LDM/glacial deposits and bedrock'. Please see line no. 304-307.

Comment 36: L261: Discussions > Discussion

Response 36: *Done. Changed 'Discussions' to 'Discussion'. Please see line no. 312.*

Comment 37: L270: alcoves > gully alcoves

Response 37: *Done. Changed 'alcoves' to 'gully alcoves'. Please see line no. 321.*

Comment 38: L272: Care needed with these citations: most early papers didn't infer high ice purity (instead preferring a rock glacier model). High confidence of ice content only came later, particularly with the radar studies.

Response 38: *As suggested, we have changed 'Mangold, 2003; Levy et al., 2009a; Morgan et al., 2009' to 'Baker et al., 2010; Plaut et al., 2009'. Please see line no. 325.*

Baker, D. M. H, James W. H., and David R. M.: Flow patterns of lobate debris aprons and lineated valley fill north of Ismeniae Fossae, Mars: Evidence for extensive mid-latitude glaciation in the Late Amazonian, Icarus 207, 186-209, 2010, doi: https://doi.org/10.1016/j.icarus.2009.11.017.

Comment 39: L273: interpreted to be comprised of > interpreted to comprise

Response 39: *Done. Changed 'interpreted to be comprised' to interpreted to comprise'. Please see line no. 324.*

Comment 40: L285: are having an elongated, V-shaped cross-section in their mid-section > do have elongated, V-shaped cross-sections in their mid-sections

Response 40: *Done. Changed 'are having an elongated, V-shaped cross-section in their mid-section' to 'do have an elongated, V-shaped cross section in their mid-sections'. Please see line no. 336.*

Comment 41: L287: perimeters and reliefs Please check pluralisation throughout

Response 41: *Done. Changed 'perimeter and relief' to 'perimeters and reliefs'. Please see line no. 338.*

Additionally, we have checked the entire manuscript for pluralization and corrected, wherever required.

Comment 42: L288: citations for 'previous studies'?

Response 42: *Done. Added 'Aston et al., 2011' as the reference for previous studies. Please see line no. 340.*

Comment 43: L370: latitudes > latitudes on Mars

Response 43: *Done. Added 'on Mars' after latitudes. Please see line no. 423.*

Comment 44: L394: ESurfD > ESurf

Response 44: *Done. Changed 'ESurfD' to 'ESurf'. Please see line no. 448.*

Morphologic and Morphometric Differences between Gullies Formed in Different Substrates on Mars: New Insights into the Gully Formation Processes

Abstract. Martian gullies are kilometer-scale geologically young features with a source alcove, transportation channel, and depositional fan. On the walls of impact craters, these gullies typically incise into bedrock or surfaces modified by latitude dependent mantle (LDM; inferred as consisting of ice and admixed dust) and glaciation. To better understand the differences in alcoves and fans of gullies formed in different substrates and infer the flow types that led to their formation, we have analyzed the morphology and morphometry of 167 gully systems in 29 craters distributed between 30°S and 75°S. Specifically we measured length, width, gradient, area, relief, and relief ratio of the gully alcoves and fans, Melton ratio, relative concavity index, and perimeter, form factor, elongation ratio and circularity ratio of the gully alcoves. Our study reveals that gully alcoves formed in LDM/glacial deposits are more elongated than the gully alcoves formed in bedrock, and possess a distinctive V-shaped cross section. We have found that the mean gradient of fans formed by gullies sourced in bedrock is steeper than the mean gradient of fans of gullies sourced in LDM/glacial deposits. These differences between gullies were found to be statistically significant and discriminant analysis has confirmed that alcove perimeter, alcove relief and fan gradient are the most important variables for differentiating gullies according to their source substrates. The comparison between the Melton ratio, alcove length and fan gradient of Martian and terrestrial gullies reveals that Martian gully systems were likely formed by terrestrial debris-flow like processes. Present-day sublimation of CO_2 ice on Mars may have provided the adequate flow fluidization for the formation of deposits akin to terrestrial debris-flow like deposits.

Formatted: Subscript

Deleted: It is likely that the present-day sublimation of CO_2 ice on Mars provided

1 Introduction

Gullies are found on steep slopes polewards of about 30° latitude in both hemispheres on Mars and manifest as kilometer-scale, geologically young features (formed within the last few million years) comprising an alcove, channel, and depositional fan (Malin and Edgett, 2000; Dickson et al., 2007; Reiss et al., 2004; Schon et al., 2009). Gullies occur in a wide assortment of settings, varying from the walls and central peaks of craters to walls of valleys, and steep faces of dunes, hills and polar pits

(e.g. Balme et al., 2006; Dickson et al., 2007; Dickson and Head, 2009; Conway et al., 2011, 2015; Harrison et al., 2015). On the walls of craters, gullies are found to have incised into (1) surfaces covered by latitude dependent mantle (LDM; e.g. Mustard et al., 2001; Dickson et al., 2012, 2015), (2) surfaces modified by former episodes of glaciation (Conway et al., 2018; de Haas 2019a; Sinha and Vijayan, 2017), and (3) bedrock (e.g. Johnsson et al., 2014; de Haas et al., 2019a; Sinha et al., 2020). Detailed investigation of the gullies formed over these different substrates is key to understanding the intricacies of past processes by which these gullies have formed on Mars (Conway et al., 2015; de Haas et al., 2019a).

A variety of models have been proposed to explain the formation of gullies, which include: (1) dry flows triggered by sublimation of CO_2 frost (e.g. Cedillo-Flores et al., 2011; Dundas et al., 2012, 2015; Pilorget and Forget, 2016; de Haas et al., 2019b), (2) debris-flows of an aqueous nature (e.g. Costard et al., 2002; Levy et al., 2010; Conway et al., 2011; Johnsson et al., 2014; de Haas et al., 2019a; Sinha et al., 2020), and (3) fluvial flows (e.g. Heldmann and Mellon, 2004; Heldmann et al., 2005; Dickson et al., 2007; Reiss et al., 2011). To better understand the gully formation processes, morphometric investigation of gullies formed over different substrates needs to be undertaken at a level of detail previously not attempted.

The global distribution of gullies shows a spatial correlation with the landforms indicative of glaciation and LDM deposition on Mars (e.g. Levy et al., 2011; Dickson et al., 2015; Harrison et al., 2015; Conway et al., 2018; de Haas et al., 2019a; Sinha et al., 2020). With respect to glacial landforms, many gullies have formed into viscous flow features (VFFs) and they are found in the same latitude ranges between 30°-60° (e.g. Arfstrom and Hartmann, 2005; de Haas et al., 2019a). VFFs are defined as an umbrella term for glacial-type formations covering a broad range of landforms that include lobate debris aprons (LDAs), concentric crater fills (CCFs), and lineated valley fills (LVFs) (e.g. Squyres, 1978; Levy et al., 2009a; Baker et al., 2010; Hargitai, 2014). Together, they are inferred to be similar to terrestrial debris-covered glaciers (Plaut et al., 2009). With respect to LDM, gullies are mostly found on the pole-facing slopes of crater walls at lower mid-latitudes (30-45°) (e.g. Balme et al. 2006; Kneissl et al. 2010; Harrison et al. 2015; Conway et al. 2017), wherein, LDM is found to be dissected (e.g. Mustard et al., 2001; Milliken et al., 2003; Head et al., 2003). In the higher latitudes (>45°), LDM is found to be continuous (e.g. Kreslavsky and Head, 2000), and gullies are evident at both the pole and equator facing slopes (e.g. Balme et al. 2006; Kneissl et al. 2010; Harrison et al. 2015; Conway et al. 2017). Gullies formed on the formerly glaciated walls of craters are fed from alcoves that do not extend up to the crater rim, and appear elongated to V-shaped, implying gully-channel incision into ice-rich, unlithified sediments (e.g. Aston et al., 2011; de Haas et al., 2019a). The alcoves, channels and fan deposits of gullies formed within craters covered by a smooth drape of LDM, are usually found to have experienced multiple episodes of LDM covering and subsequent reactivation of some of the pre-existing channels or formation of fresh channels within the draped LDM deposits (e.g. Dickson et al., 2015; de Haas et al., 2019a). Additionally, there are gullies that directly emanate from well-defined bedrock alcoves that cut into the crater rim in the absence of LDM and/or glacial deposits (e.g. Johnsson et al., 2014; de Haas et al., 2019a; Sinha et al., 2020). Gullies formed in these craters have alcoves with sharply defined crests and spurs, exposing the underlying bedrock, and meter-sized boulders are found throughout the gully system (e.g. Johnsson et al., 2014;

Deleted: the

Deleted: Hubbard et al., 2011; Souness et al., 2012; Souness and Hubbard, 2012

Deleted: extent of latitudes

Deleted: 8

Deleted: Conway et al., 2018

de Haas et al., 2019a; Sinha et al., 2020). Further, De Haas et al., 2015a found that the stratigraphy of the fans whose source area was in bedrock were more boulder-rich than those fans fed by catchments in LDM. The findings in these studies suggest that a more detailed investigation of the morphology and morphometry of the gullies formed over contrasting substrates is important for improving our understanding of the formative mechanisms of gullies.

In this work, we focus on addressing the following research questions:

(1) Do the morphologies and morphometries of gully systems formed in different substrates differ (i.e. LDM/glacial deposits and bedrock)?

(2) How do the morphometric characteristics of gullies formed on Mars compare to those formed by a range of processes on Earth, and what does that tell us about the formative processes of Martian gullies?

To parameterize the morphometry we will primarily study long profiles. Previously, only a few studies have analyzed the morphometric characteristics of the gullies by studying their long profiles (e.g. Yue et al., 2014; Conway et al., 2015; De Haas et al., 2015a; Hobbs et al., 2015). These studies have focused observations on a part of the gully system and suggested that the differences in the properties of substrate into which the gullies incise play a significant role in promoting the flows that led to gully formation. Hence, for a more detailed differentiation of the gully types and interpretation of the dominant flow type that led to gully formation on Mars, quantification of the morphometric characteristics of the entire gully system is crucial.

2 Study sites and datasets

We characterize the morphologies and morphometries of gullies in 29 craters distributed over the southern hemisphere of Mars between 30° S and 75° S latitude (Fig. 1). These 29 craters are selected based on the availability of publicly released High Resolution Imaging Science Experiment (HiRISE) stereo-pair based digital terrain models (DTMs) or the presence of suitable HiRISE stereo-pair images to produce a DTM ourselves. The HiRISE stereo-pair images are usually ~0.25 - 0.5 m/pixel (McEwen et al., 2007), so the DTM post spacing is ~1-2 m with vertical precision in the range of tens of centimeters (Kirk et al., 2008). Among the 29 gullied craters, publicly released DTMs are available for 25 craters (https://www.uahirise.org/hiwish/maps/dtms.jsp - last accessed 18th September 2021) (Table 1). For the remaining 4 craters, we produced DTMs with the software packages USGS ISIS and BAE Systems SocetSet (Table 1) (Kirk et al., 2008). We investigated HiRISE images of these 29 gullied craters for detailed morphological characterization of the substrate into which the crater wall gullies incise (Table 1).

334 **3 Approach**

335 **3.1 Identification of substrate**

336 The substrate into which the gullies have incised is identified based on the following criteria:

337 1. LDM/glacial deposits: Any crater whose gullies incise walls that appear to be softened by the drape of smooth mantling
338 material with polygonal cracks is inferred to have LDM as the substrate within which gullies have incised (e.g. Mustard et al.,

2001; Kreslavsky and Head, 2002; Levy et al., 2009a; Conway et al., 2018; de Haas et al., 2019a) (Fig. 2a-b). The gully alcoves on the walls of these craters may be partially to completely filled by LDM, and in some cases, polygonized LDM materials may be seen covering the alcove walls (e.g. Christensen, 2003; Conway et al., 2018; de Haas et al., 2019a). These infilled alcoves on the crater walls are not the alcoves of gullies formed within the LDM substrate; instead, they represent the alcoves that were formed prior to the LDM emplacement epoch. Additionally, gullied craters that show evidence in the form of arcuate ridges at the foot of the walls and VFFs that cover part or the entire crater floor are inferred to have been modified by one or multiple episodes of glaciation (e.g. Arfstrom and Hartmann, 2005; Head et al., 2010; Milliken et al., 2003; Hubbard et al., 2011) (Fig. 2c). These craters host gullies that are often partially or fully covered by LDM deposits and are also inferred to incise LDM deposits.

2. Bedrock: Craters where the features listed in criterion 1 (LDM/glacial deposits) are absent and where rocky material is visible extending downwards from the crater rim (Fig. 2d). This rocky material usually outcrops as spurs and can be layered or massive. The slopes can be smooth or covered with boulders, with concentrations of boulders at the slope toe.

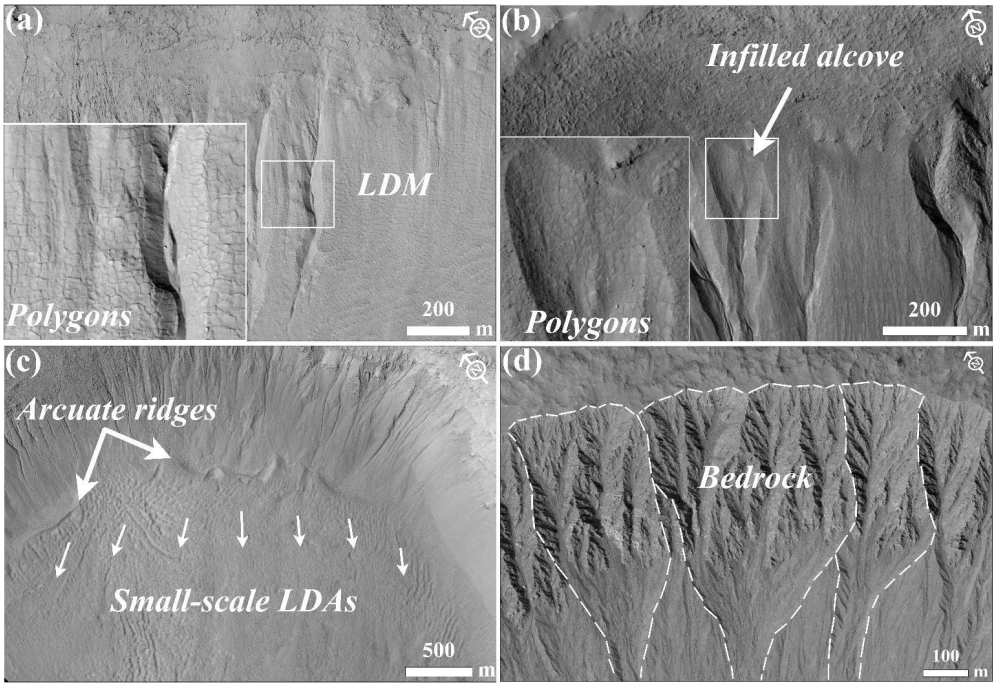

Figure 2: Examples of morphological evidence used to identify LDM, glacial deposits, and bedrock. (a) Smooth mantling material inferred as LDM draped on the wall of Talu crater on the basis of polygonal cracks formed in the material. The bigger box is an expanded view of the polygons seen over the region outlined by the smaller box. (HiRISE image ESP_011817_1395). (b) An infilled alcove on the wall of an unnamed crater-2 in Terra Sirenum. Polygons in the infilled material suggests presence of LDM deposits draped on the wall. The region shown in smaller box is expanded in the bigger box to show evidence of the polygons. (HiRISE image ESP_020407_1410). (c) Glaciation inferred in the Corozal crater on the basis of arcuate ridges formed at the foot of the crater wall and small-scale LDAs on the crater floor. Arrows indicate the downslope flow of LDAs on the floor. (HiRISE image PSP_006261_1410). (d) Exposed fractured bedrock identified on the walls of Istok crater within which gully alcoves have incised. 3.2 Morphometric variables

The measurements we made of each gully system include alcove area, alcove perimeter, alcove length, alcove width, alcove gradient, fan area, fan length, fan width, and fan gradient (Fig. 3). In total, we derived 18 morphometric variables to characterize each gully fan and its alcove. The morphometric variables are classified into geometry, relief, gradient, and dimensionless variables (e.g. form factor, elongation ratio, and circularity ratio) and they are calculated with established mathematical equations shown in Table 2. For the gradient measurement using the DTM, the topographic profile from (1) crest of the alcove to the apex of the fan was extracted for the alcove, and (2) apex to foot of the fan was extracted for the fan.

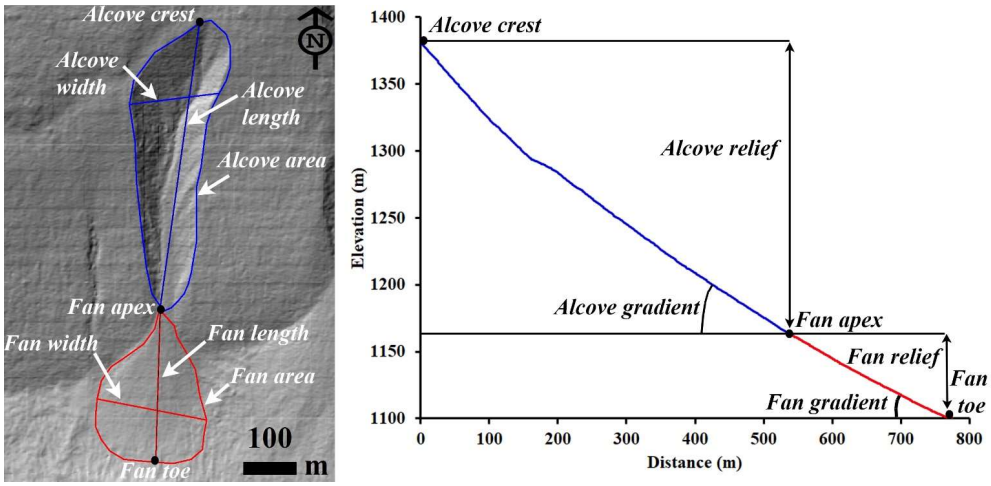

Figure 3: Examples of morphometric variables estimated in this work. Left panel: HiRISE DTM (Id: DTEEC_002659_1420_002514_1420) based hillshade. HiRISE DTM credit: NASA/JPL /University of Arizona. Right panel:

Topographic profile: blue profile represents the topography of gully alcove from alcove top to fan apex and red profile represents the profile of gully fan from fan apex to fan toe.

Table 2. Set of morphometric variables extracted from the studied gully systems and their formulas and/or description of method.

Morphometric variable	Formula and/or description of method	References
Alcove length and width	Measured in km	**Tomczyk, 2021**
Alcove area	Measured in km^2	**Tomczyk, 2021**
Fan length and width	Measured in km	**Tomczyk, 2021**
Fan area	Measured in km^2	**Tomczyk, 2021**
Melton ratio	(Alcove relief)/(Alcove area$^{-0.5}$)	**Melton, 1957**
Relative concavity index (RCI)	Concavity Index/(maximum relief between the uppermost and lowermost points along the gully fan profile/2). Concavity Index is estimated as $\sum (H_i^* - H_i) / N$, where H_i^* is the elevation along the straight line, H_i is the elevation along the gully fan profile, N is the total number of measurement points.	**Langbein, 1964; Phillips and Lutz, 2008**
Alcove gradient	Measured in (°)	**Tomczyk, 2021**
Fan gradient	Measured in (°)	**Tomczyk, 2021**
Alcove relief	Measured in km	**Tomczyk, 2021**
Fan relief	Measured in km	**Tomczyk, 2021**
Relief ratio (alcove and fan)	Alcove/fan relief divided by the length of the alcove/fan	**Schumm, 1956a, b**
Alcove Perimeter	Measured in km	**Schumm, 1956a, b**
Form factor	Alcove area divided by the square of the length of the alcove	**Horton, 1932**
Elongation ratio	Diameter of a circle of the same area as the alcove divided by the maximum alcove length	**Schumm, 1956a, b**
Circularity ratio	Alcove area divided by the area of the circle having the same perimeter as the alcove perimeter	**Miller, 1953**

3.3 Gully system selection for morphometric measurements

We have selected only those gully systems for morphometric measurements in which: (i) the depositional fan from an alcove-channel system is not superimposed by or interfingering with the fans from the neighboring channels, (ii) there is clear association between the primary channel emanating from the alcove that extends downslope and then deposit its respective fan, (iii) no evidence of extensive cross-cutting is seen with the neighboring channels on the walls, (iv) no evidence of extensive mantling by dust/aeolian deposits is apparent, and (v) no evidence of channel/fan superposition on any topographic obstacle on the walls or the floor of the crater is apparent, which may have influenced the morphometry. If in any case the fans

superimpose or channels cross-cut, we have carefully demarcated the alcove-channel-fan boundary, to minimize the inaccuracies in the measurements. Note that the selection of the gully systems was also constrained by the coverage of HiRISE DTMs used for morphometric analysis.

3.4 Statistical analysis of morphometric variables

We have two groups of gullies in our study: (1) gullies whose source areas are incised into LDM/glacial deposits and (2) gullies whose source areas are incised into the bedrock. First, for both the groups we have calculated descriptive statistics for each of the morphometric variables shown in Table 2. The significance of the difference between the values of each of the morphometric variables calculated for each group was tested using a Student's t-test. To apply t-tests, we have transformed the morphometric variables to remove skewness by taking their natural logarithm. Pearson correlation analysis has been used to investigate the correlation between the selected morphometric attributes of gully alcoves and fans. We infer strong positive correlations between variables if the correlation coefficient value is more than 0.7 and strong negative correlations if the value is less than -0.7. Very strong positive correlation between variables is inferred if the correlation coefficient is ≥0.9. Further, we used canonical discriminant analysis (CDA) to determine morphometric variables that provide the most discrimination between the groups of gullies. In CDA, functions are generated according to the number of groups, until a number equal to n-1 functions is reached (n is the number of groups) (McLachlan, 2005). For the two groups of gullies in our study, there is going to be a function for which there is a standardised canonical discriminant function coefficient associated with the morphometric variable. The higher the magnitude of this coefficient for a particular morphometric variable, the higher the role of that variable in separating the groups of gullies (Conway et al., 2015). Standardisation was done by dividing each value for a given variable by the maximum value.

4 Results

4.1 Morphology of gully systems

Out of the 29 gullied craters analysed in this work, we have found that there are 24 craters influenced by LDM and/or VFFs. The remaining 5 craters have gullies incised into the exposed underlying bedrock on the wall of the crater. Below we describe the substrates identified in the studied craters and then compare the morphology of the gullies formed into those substrates.

4 craters out of 24 craters (i.e. Raga, Roseau, unnamed crater in Newton basin and unnamed crater-1 in Terra Sirenum) have gullies that are only influenced by LDM. In these craters, we have found morphological evidence of LDM in the form of polygonized, smooth textured material on the pole-facing walls of the craters. Morphological evidence of VFF is not evident in these craters. In these craters, the gully-alcoves and gully channels appear to have been incised into the polygonized LDM material, and the gully-fan deposits are mantled. A typical example of this can be found in the unnamed crater formed inside the Newton basin (Fig. 4a). Roseau crater, in particular, contains a large number of gully systems whose alcoves and fans are

Deleted: that was

Deleted: is

Deleted: is

Deleted: Correlation

Deleted: (Conway et al., 2015)

extensively mantled (Fig. 4b). The remaining 20 out of 24 craters contain evidence for gullies that are influenced by both LDM and glacial deposits (Table 1). The base of the pole-facing walls and the floor of the craters within which the gully systems have formed host linear-to-sinuous arcuate ridges and VFFs, respectively. Typical examples of VFFs can be found in Corozal, Talu, unnamed craters in Terra Sirenum and Argyre basin, Langtang, Dechu and Dunkassa craters (Fig. 4c). In majority of the gullied craters (except Raga, Roseau and unnamed crater-1 in Terra Sirenum) influenced by LDM and glacial deposits, gully alcoves are found to have a distinctive V-shaped cross section in their mid-section (Figures 4d and 4e), they do not extend up

to the crater rim, and gully systems often show multiple episodes of activity, inferred by the presence of fresh channel incision on the gully-fan surfaces (Fig. 4d-e).

Istok, Galap, Gasa, Los, and an unnamed crater in the Terra Sirenum contain gully systems on the pole-facing walls that are not associated with LDM and VFFs (Table 1). The gully alcoves inside these craters have a crenulated shape and appear to have formed by headward erosion into the bedrock of the crater rim (Fig. 4f). These craters have formed large gully systems on their pole-facing walls, with brecciated alcoves, comprising of multiple sub-alcoves and hosting many clasts/boulders (Fig. 4f).

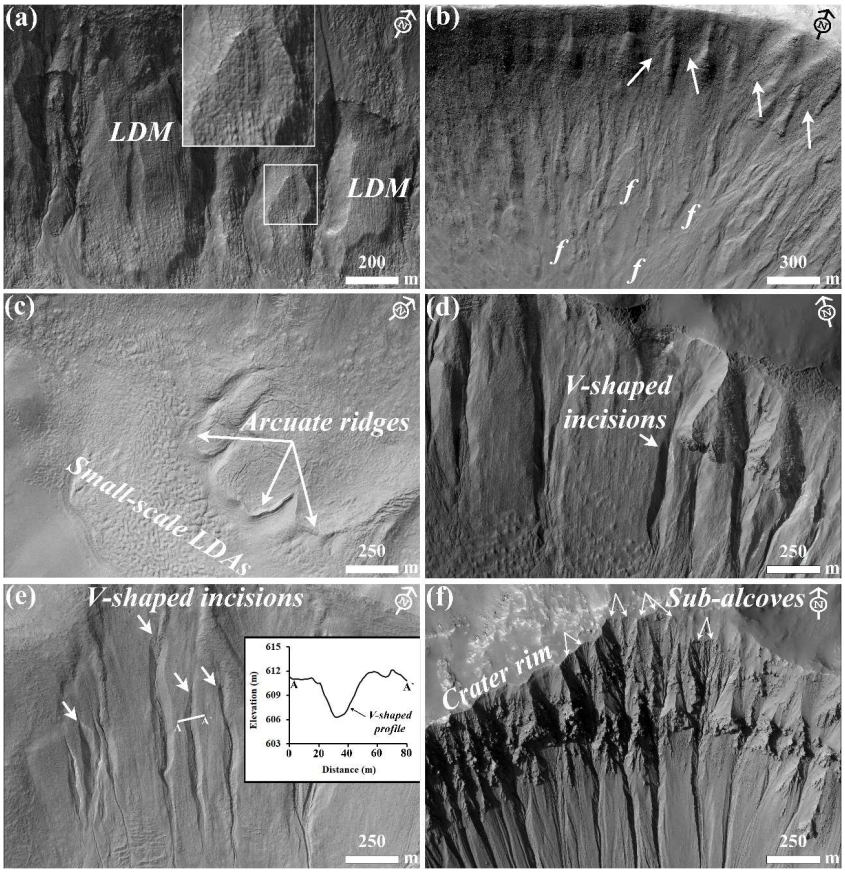

Figure 4: (a) LDM draped on the wall of an unnamed crater in the Newton basin. The inset shows details of the polygonal texture of the LDM. (HiRISE image PSP_002686_1410). (b) Infilled gully alcoves (arrows) and mantled fan surfaces (marked by letter 'f') on the wall of Roseau crater. (HiRISE image ESP_024115_1380). (c) Arcuate ridges at the foot of the crater wall and small-scale LDAs on the floor in Langtang crater. (HiRISE image ESP_030099_1415). (d) V-shaped incisions on the LDM draped walls of Taltal (HiRISE image ESP_037074_1400) and (e) Langtang crater (HiRISE image ESP_030099_1415). Note the topographic profile (A-A`) that illustrates V-shaped incision of the gully channel. (f) Gully alcoves formed in Los crater by headward erosion into the crater rim. Individual gully alcoves formed in bedrock have multiple sub-alcoves. (HiRISE image ESP_020774_1445).

4.2 Morphometry of gully systems

Based on the criteria summarized in section 3.3, we have studied 167 gullies across 29 craters for calculation of morphometric variables. 130 gullies are formed within LDM/glacial deposits, and 37 gullies are formed within the bedrock. The results of morphometric calculations are summarized for visual comparison as a boxplot (Fig. 5).

The results of the Student's t-test indicates that all of the morphometric variables in Table 2, except fan width, fan area, Melton ratio, form factor, elongation ratio, and circularity ratio, differ significantly between LDM/glacial deposits and bedrock (Fig. 5). Compared to the mean gradient of gully-fans formed in LDM/glacial deposits, bedrock gully-fans are steeper and possess a higher relief ratio. The interquartile range of length, relief, and perimeter of gully alcoves formed in bedrock are also higher than the interquartile range of similar variables in LDM/glacial deposits, but the gully alcoves in LDM/glacial deposits possess much higher values of length, relief, and perimeter (Fig. 5).

Pearson correlations between morphometric attributes of gully alcoves and fans formed in bedrock and LDM/glacial deposits are summarized in Fig. 6. For bedrock, there are strong positive correlations between 12 pairs of morphometric variables and strong negative correlations between 3 pairs of morphometric variables. For LDM/glacial deposits, there are strong positive correlations between 18 pairs of morphometric variables and strong negative correlations between 3 pairs of morphometric variables. Very strong positive correlations (>0.9) are found between 9 pairs of morphometric variables for bedrock and between 4 pairs of morphometric variables for LDM/glacial deposits.

Deleted: Higher the value of the correlation coefficient, higher is the strength of the correlation

The canonical discriminant analysis reveals that the following morphometric variables best distinguish between the gully systems formed in LDM/glacial deposits and bedrock, in descending order of importance: alcove perimeter, alcove relief, fan gradient, fan relief, fan length, relief ratio (alcove), alcove width, relief ratio (fan), alcove gradient, alcove area, alcove length, and relative concavity index (Table 3). The alcove perimeter is most important in discriminating among the gully systems formed within LDM/glacial deposits and bedrock, and the next two most important variables are alcove relief and fan gradient. Alcove relief and fan gradient have 4/5 and 1/3 the weight of alcove perimeter, respectively. Here, the weight values indicate

the discriminator power in separating between the gullies formed in LDM/glacial deposits and bedrock. The remaining variables such as fan relief, fan length, relief ratio (alcove), alcove width, and relief ratio (fan) have nearly 1/5 or greater (but less than 1/3) of the weight of alcove perimeter discriminatory power in separating between the gullies formed in LDM/glacial deposits and bedrock. The variables with the smallest magnitude, alcove gradient, alcove area, alcove length and relative concavity index, have less than 1/10 the weight of the most important variable in separating the gully systems.

Table 3. Standardised canonical discriminant function coefficients (F1) that best separate gully systems formed on LDM/Glacial deposits and bedrock.

Variable	F1
Alcove Perimeter	3.552
Alcove relief	-2.828
Fan gradient	1.278
Fan length	-1.06
Fan relief	1.06
Relief ratio (alcove)	0.971
Alcove width	-0.692
Relief ratio (fan)	-0.665
Alcove gradient	-0.331
Alcove area	-0.319
Alcove length	0.23
Relative concavity index	-0.182

5 Discussion

5.1 Unique morphology and morphometry of gully systems in different substrates

We have found that the gully systems formed in LDM/glacial deposits and bedrock can, using discriminatory analysis, be distinguished from one another in terms of perimeter and relief of gully alcoves (Table 3). Additionally, we have found statistically significant difference between the perimeters and reliefs of gully alcoves formed in LDM/glacial deposits and bedrock (Fig. 5). It is likely that these differences in the perimeters and reliefs of gully alcoves formed within morphologically distinct substrates could be due to the integral nature of the surface material within which the gully alcoves have formed. In other words, it is possible that the differences in the physical properties of the sediments (namely grain size, compactness etc.) within which gully alcoves have formed played a key role in erosion of the substrate leading to differences in their

Deleted: the weight of alcove perimeter or greater

Deleted: s

morphometric variables. Below we elaborate on the uniqueness of the substrates within which gully alcoves have formed, and discuss further the relationships between the morphometric variables of the morphologically distinct gully systems.

On Mars, VFFs contain high purity glacial ice with a debris cover (Sharp, 1973; Squyres, 1978, 1979; Squyres and Carr, 1986; Holt et al 2008, Plaut et al 2009, Petersen et al. 2018). Their surfaces have been interpreted to comprise of finer, reworked debris derived from sublimation of the underlying ice (Baker et al., 2010; Plaut et al., 2009). The smooth, meters thick draping unit on the walls of formerly glaciated craters has been suggested to be derived from the atmosphere as a layer of dust-rich ice primarily constituting of fine-grained materials (Kreslavsky and Head, 2000; Mustard et al., 2001). The fine-grained materials are loosely-packed, unconsolidated materials exhibiting low thermal inertia values (Mellon et al., 2000; Putzig et al., 2005). Typically, gullies formed within this substrate display a smooth surface texture, wherein, evidence of individual clasts or meter-scale boulders is not resolvable in HiRISE images, substantiating the dominant component of fine-grained materials within the LDM (e.g., Levy et al., 2010; de Haas et al., 2015a). Additionally, it has been found that gully alcoves incised into the LDM always have a distinctive V-shaped cross section in their mid-section (Figures 4d and 4e), which when compared with similar-scaled systems on Earth also corresponds to the presence of loose sediments constituting the LDM (Conway et al., 2018). The gully alcoves with V-shaped cross sections are found to be elongated, likely indicating incision within ice-rich unlithified sediments (Aston et al., 2011). In the studied craters, we have found that gullies incised into LDM/glacial deposits do have an elongated, V-shaped cross section in their mid-sections (Fig. 4). We propose that the presence of fine-grained, loosely packed, unconsolidated materials within LDM/glacial deposits has facilitated formation of elongated gully alcoves with perimeters and reliefs relatively higher than that of gully alcoves formed in coarse-grained bedrock substrate. This is consistent with the previous studies suggesting that gullies eroding into LDM/glacial deposits have elongated catchments (Aston et al., 2011), whereas gullies eroding into the bedrock have more amphitheater-shaped catchments (Levy et al., 2009b). For this reason, the estimated length of gully alcoves formed in LDM/glacial deposits is found to be relative higher than that of gully alcoves formed in bedrock (Fig. 5). Furthermore, statistical analysis has revealed a significant difference between the length of gully alcoves formed in LDM/glacial deposits and bedrock (Fig. 5). Additionally, the presence of finer-grained sediments in LDM/glacial deposits is the likely cause of the V-shape of the incision of gully alcoves investigated in this study (Aston et al., 2011). On Earth, V-shaped incisions through glacial ice-rich moraines have been observed to have occurred during the paraglacial phase of glacial retreat (Bennett et al., 2000; Ewertowski and Tomczyk, 2015) (Fig. 7). The paraglacial phase refers to a terrestrial post-glacial period that represents the response of changing environment to deglaciation (Bennett et al., 2000; Ewertowski and Tomczyk, 2015).

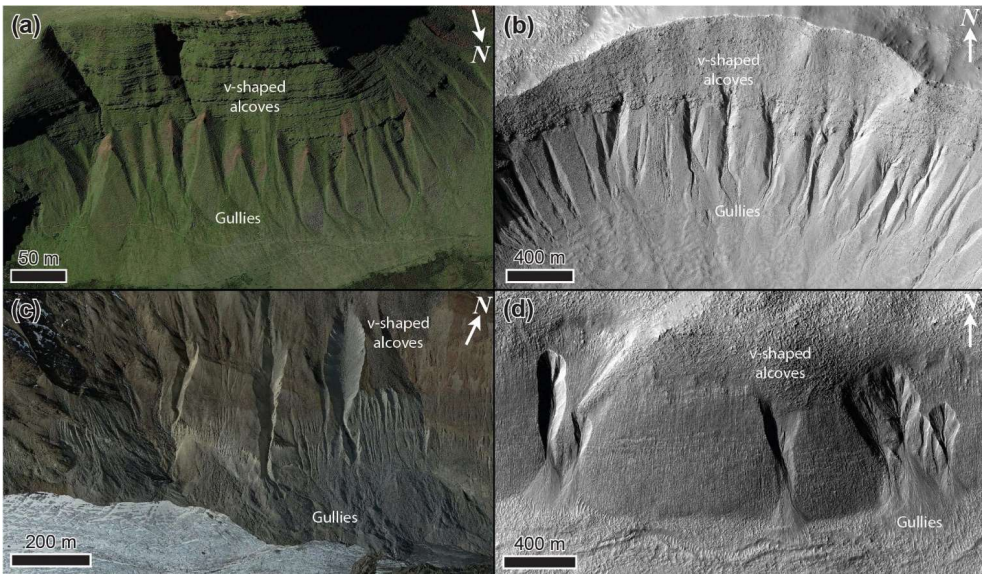

Figure 7: Gullies forming in glacial sediments in deglaciated terrain in the (a) Brecon Beacons, Wales, UK on Earth (Google Earth coordinates: 51°52'59.11"N, 3°43'33.26"W), (b) Talu crater (https://www.uahirise.org/ESP_011817_1395) on Mars, (c) Hintereisferner, Austria (Google Earth coordinates: 46°48'54.25"N, 10°47'8.18"E), on Earth, and (d) Bunnik crater (https://www.uahirise.org/ESP_047044_1420) on Mars. HiRISE image credit: NASA/JPL-Caltech/University of Arizona.

The next most important difference between these two types of gullies is the mean gradient of gully fans. At the foot of the fans, mean gradient of the fans influenced by LDM/glacial deposits is <15° for 61% of the studied fans. For bedrock, 84% of the studied fans have a mean gradient >15° at the foot of the fans. Hence, gully-fans formed in bedrock are emplaced at a relatively steeper gradient than the fans formed from gullies in LDM/glacial deposits. We propose that the nature of the material mobilized can explain this difference, with the finer-grained sediments characteristic of the LDM/glacial type gullies being easier to mobilise and being entrained to lower slope angles, than the coarser sediments found within the bedrock type gullies.

5.2 Evaluation of the gully formation process

On Earth, alcove-fan systems can roughly be subdivided in flood-dominated, debris-flow dominated, and colluvial systems. Following the terminology of De Haas et al., (2015b) and Tomczyk (2021), we define these systems as follows:

1) Flood-dominated systems: These are systems dominated by fluid-gravity flows, i.e., water floods, hyperconcentrated floods, and debris floods. The fans of such systems are commonly referred to as fluvial or alluvial fans (e.g., Ryder, 1971; Blair and McPherson, 1994; Hartley et al., 2005).

2) Debris-flow dominated systems: These are systems dominated by sediment-gravity flows, i.e., debris flows, mud flows. Irrespective of their radial extent and depositional gradients, the fans aggraded by these systems can be commonly called debris-flow fans or debris fans (Blikra and Nemec, 1998; de Scally et al., 2010).

3) Colluvial systems: These are systems dominated by rock-gravity and sediment-gravity flows, with their dominant activity relating to rockfalls, grain flows, and snow avalanches (in periglacial and alpine settings). Debris flows typically constitute only a relatively minor component of geomorphic processes in such systems. The fans of these systems are also commonly known as colluvial cones or talus cones (Siewert et al., 2012; De Haas et al., 2015b).

Although these systems may be dominated by one type of geomorphic process, it is important to stress that other processes may also occur. For example, on Earth water floods are not uncommon on many debris-flow dominated systems, while debris-flow deposits are commonly recognized on colluvial cones.

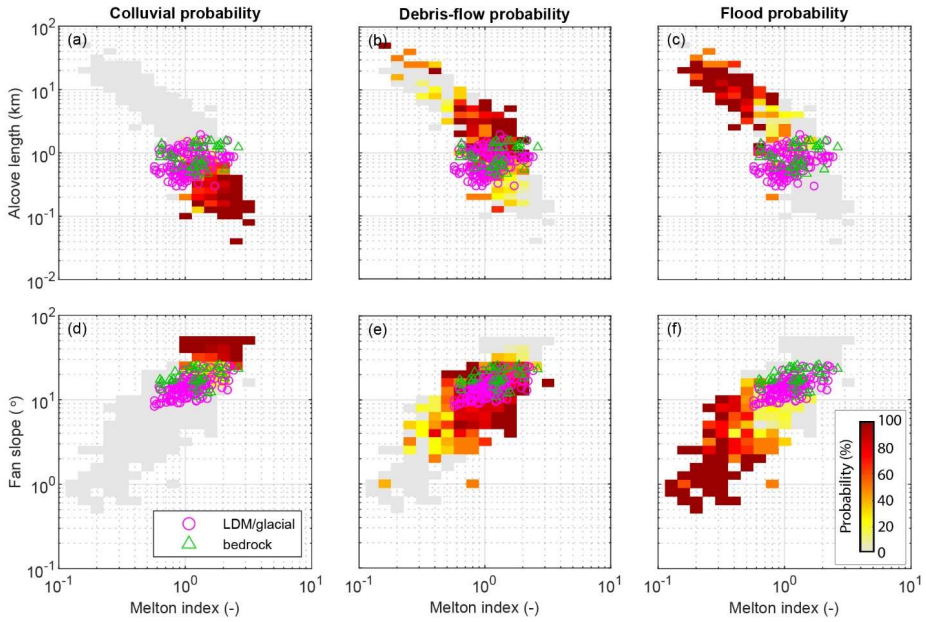

Figure 8: Comparison of combinations of Melton ratio with Alcove length and Fan gradient. The probability heat maps are based on previously published data – see text for references. The Martian gully systems formed in LDM/glacial deposits and bedrock are found to be in the debris-flow regime on Earth. The gray area shows the realm of the colluvial, debris-flow, and fluvial fans together.

To compare the morphometric characteristics of the Martian gully systems to terrestrial systems, we have compiled morphometric data of gully alcoves and fans across several continents, mountain ranges, climate zones, and process types on Earth. This dataset includes published data from the Himalayas, Ladakh, India (Stolle et al., 2013), the tropical Andes, Columbia (Arango et al., 2021), Spitsbergen, Svalbard (Tomczyk, 2021), British Columbia, Canada (Kostaschuk, 1986; Jackson et al., 1987; and newly presented data), the southern Carpathians, Romania (Ilinca et al., 2021), the Southern Alps, New Zealand (De Scally and Owens, 2004; De Scally et al., 2010), the North Cascade Foothills, USA, the European Alps (including Switzerland, Italy, France, and Austria), and the Pyrenees (from multiple authors compiled by Bertrand et al., 2013). The dataset comprises information from colluvial, debris-flow, and flood (also including debris flood) dominated systems. In

total, it contains 231 colluvial systems, 749 debris-flow dominated systems, and 369 flood-dominated systems. In total, data were compiled for 1349 systems, although not all information was available for all systems, with data availability ranging from 729 sites for alcove length to all 1349 systems for Melton index and process type. Based on this data we have made a heatmap of the probability of flood, debris-flow, or colluvially-dominated conditions for combinations of Melton ratio with alcove length and fan gradient, to which we compare the Martian gullies (Fig. 8). We have specifically chosen the combinations of Melton ratio with alcove length and fan gradient to infer the Martian gully formative mechanism because they have been widely used in discriminating terrestrial drainage basins and fans prone to flooding from those subject to debris flows, debris floods and floods (e.g. De Scally and Owens, 2004; Wilford et al., 2004). We have found that the Martian gullies are indeed in the debris-flow regime on Earth. Moreover, they are closer to the transition to the smaller and steeper colluvial cones than to transition to flood-dominated fans. As expected, bedrock systems in Fig. 8d-e are closer to the colluvial systems than the LDM systems.

According to the previous reports of debris-flow like deposits found in Martian gullies (e.g. Johnsson et al., 2014; Sinha et al., 2019, 2020), the morphological attributes of debris-flow like deposits typically include overlapping tongue-shaped lobes with embedded clasts, channels with medial deposits, and channels with clearly defined lateral levees. Although it is still not clear whether the formation of these deposits in gullies are from sublimation of CO_2 ice or due to meltwater generation. De Haas et al., (2019b) showed that CO_2 sublimation may lead to flow fluidization on Mars in a manner similar to fluidization by water in terrestrial debris flows; a concept supported by the recent finding of lobate deposits and boulder-rich levee formation during the present-day in Istok crater (Table 1) (Dundas et al., 2019). The formation of these morphologically similar deposits during the present-day is attributed to sublimating CO_2 frost, which likely produces the necessary fluidization likely by gas generated from entrained CO_2 frost (Dundas et al., 2019). On the basis of these recent reports (De Haas et al., 2019b; Dundas et al., 2019) and based on our own findings in this study, we argue that a debris-flow like process similar to those operated in the terrestrial gully systems has likely dominated the flow types that lead to gully formation on Mars. Present-day sublimation of CO_2 ice on Mars may have provided the necessary flow fluidization for the emplacement of deposits similar to terrestrial debris-flow like deposits (De Haas et al., 2019b).

6 Conclusions

This paper compares morphological and morphometric characteristics of gully alcoves and associated fans formed in LDM/glacial deposits and bedrock over walls of 29 craters between 30° S and 75° S latitudes on Mars. 5 craters out of 29 have alcoves-fans formed within the bedrock and remaining 24 craters have alcoves-fans formed within LDM/glacial deposits. From our analysis of 167 gullies, we posit that gully systems formed in LDM/glacial deposits and bedrock differ from one another using the following lines of evidence:

• Gully alcoves formed in LDM/glacial deposits are more elongated than the gully alcoves formed in bedrock, and possess a distinctive V-shaped cross section.

• The mean gradient of gully-fans formed in bedrock is steeper than the mean gradient of fans formed from gullies in LDM/glacial deposits.

The morphological distinction reported between gullies formed in the bedrock and LDM/glacial deposits signifies that Martian gullies may have multiple formative environments. We infer that the presence of mantling material could be one of the key factors in constraining the mechanisms forming Martian gully systems and that presence of LDM would promote formation of elongated gully alcoves with perimeters and reliefs relatively higher than that of gully alcoves formed in coarse-grained bedrock substrate.

Based on the combinations of Melton ratio with alcove length and fan gradient, we suggest that the gully systems studied in this work were likely dominated by terrestrial debris-flow like processes during their formation. This is consistent with the findings reported in previous studies that showed evidence of formation of deposits morphologically similar to terrestrial debris-flow like deposits, both in the past and during the present-day (e.g., Johnsson et al., 2014; Dundas et al., 2019). The present-day sublimation of CO_2 ice on Mars is envisaged to provide the necessary flow fluidization for the emplacement of deposits similar to debris-flow like deposits on Earth (De Haas et al., 2019b).

7 Author contribution

RKS, TDH and SJC conceptualized this work. The methodology was developed by RKS, TDH and SJC. Data curation and formal analyses were performed by RKS. TDH and AN also contributed in collection of datasets used in this work. RKS, DR, TDH and SJC contributed to the interpretation of the data and results. RKS wrote the original draft of this paper, which was reviewed and edited by all authors.

8 Conflict of interest

SJC is a Guest Editor of this special issue (Planetary landscapes, landforms, and their analogues) of ESurf and on the editorial board for ESurf. The peer-review process was guided by an independent editor, and the authors have also no other competing interests to declare.

9 Acknowledgements

We are grateful and thank both the anonymous reviewers for thorough assessment of our manuscript and for providing us constructive comments and suggestions. Thanks to the Editor (Heather Viles) and Associate Editor (Frances E. G. Butcher) at Earth Surface Dynamics for the editorial handling of the manuscript. We would like to thank the HiRISE team for their work to produce the images and digital elevation models used in this study, it would have been impossible without them. RKS and
